

ACID PROPERTIES IN SQL

Acid properties in sql is basically when your transaction is execution

- Transaction – query
Select * from employees ;
So this whole query is called a transaction

A- AUTOMICITY

EITHER THE TRANSACTION WILL FULLY EXECUTE OR THERE IS AN ERROR IT IS AUTOMATICALLY TERMINATED

Select * from employees;

Even if there is small mistake the transaction will not execute it will give error

C- CONSISTENCY

That your data is consistent irrespective of the changes you are doing in the table

For ex if you create a table with some records it will be there even if you change the table name , it will be there

- I (isolation)

Transaction are independent of each other

Select * from employees

Select * from employees where salary =50000;

Both transactions are independent until you don't execute by selecting

D- durability

Once your table is created and records are there it will going to be there forever until you delete it

Difference between consistency and durability

Consistency makes your data consistent basically data types not changes , it does not affect existing records in the table

Durability helps in protecting data from getting lost it remains in your database forever until you delete it
